

Cancer Cell Metabolism

The transcription of the fatty acid synthase gene is upregulated in a number of cancer types, including breast, colon, and prostate. This upregulation is associated with increased proliferation and is a hallmark of cancer cells. The transcription of the fatty acid synthase gene is upregulated in a number of cancer types, including breast, colon, and prostate. This upregulation is associated with increased proliferation and is a hallmark of cancer cells.

- Glucose metabolism
- ATP synthesis
- Cholesterol synthesis
- Fatty acid synthesis
- Lipid synthesis
- One-carbon metabolism
- Protein synthesis
- Cellular signaling
- Cellular growth
- Cellular differentiation
- Cellular death
